

To prevent accidents arising from the misuse of this controller, please ensure the operator receives this manual. For this product to which communication function has been added, "1" is entered at the end of the model number. (For the model number and basic operation, refer to the instruction manual for KT2.)

Warning

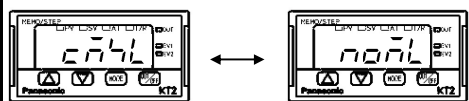

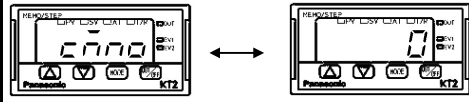

Turn the power supply to the instrument off before wiring or checking.

Working or touching the terminal with the power switched on may result in severe injury or death due to Electric Shock.

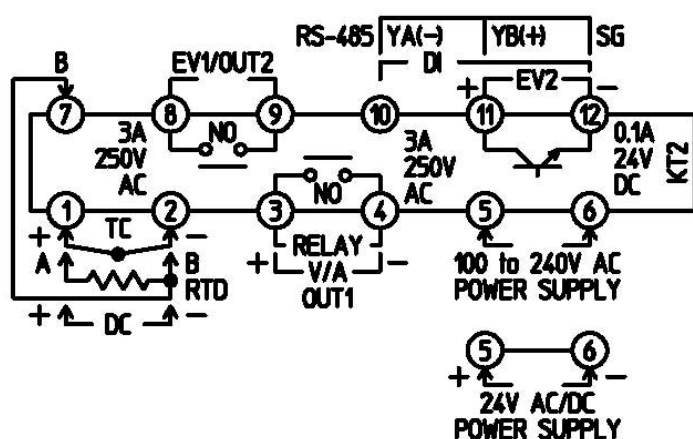

1. Setup of the KT2

Set the items "Communication protocol selection", "Instrument number setting", "Communication speed selection" after the "Sensor correction setting" in Auxiliary function setting mode 1.

To enter Auxiliary function setting mode 1, press the **MODE** key for 3 seconds while holding down the  key.

Display	Name, Functions, Setting range	Default value
	Communication protocol selection • Selects the communication protocol. • <i>na</i> : Unavailable <i>naA</i> : Modbus ASCII mode <i>naR</i> : Modbus RTU mode	Modbus ASCII mode
	Instrument number setting • Sets the instrument number individually to each instrument when communicating by connecting plural instruments in serial communication. • Setting range: 0 to 95 (However, number of connectable units: Max. 31 units)	0
	Communication speed selection • Selects a communication speed to be equal to the speed of the host computer. • <input type="checkbox"/> 24: 2400bps <input type="checkbox"/> 48: 4800bps <input type="checkbox"/> 96: 9600bps <input type="checkbox"/> 192: 19200bps	9600bps

2. Terminal arrangement

(Fig. 2-1)

- TC : Thermocouple input terminals
- RTD : RTD input terminals
- DC : DC current, DC voltage input terminals
For DC current input type, connect 50Ω shunt resistor (sold separately) between input terminals.
- OUT1 : Control output or Heating output (Heating/Cooling control option) terminals
- POWER SUPPLY: Power terminals
- EV1/OUT2: Event output 1 or Cooling output (Heating/Cooling control option) terminals
- EV2 : Event output 2 terminals
- DI : DI (Digital input) terminals
Three DI functions: SV1/SV2 external selection function, OUT/OFF (RUN/STOP) external selection and Timer function
- RS-485: Serial communication terminals

3. System configuration

RS-485 multi-drop connection communication

(Fig. 3-1)

(Fig. 3-2)

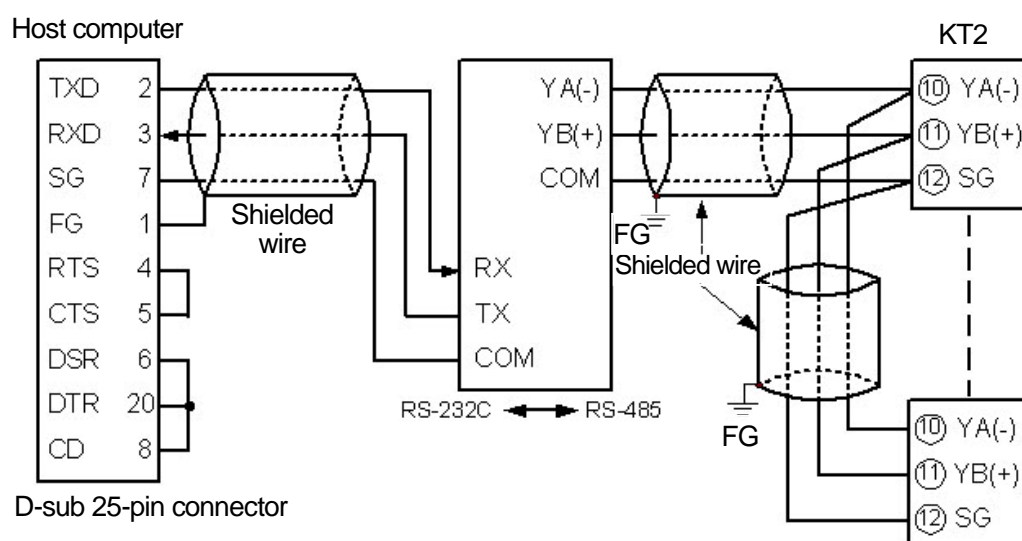

(Fig. 3-3)

4. Wiring

When using a communication converter

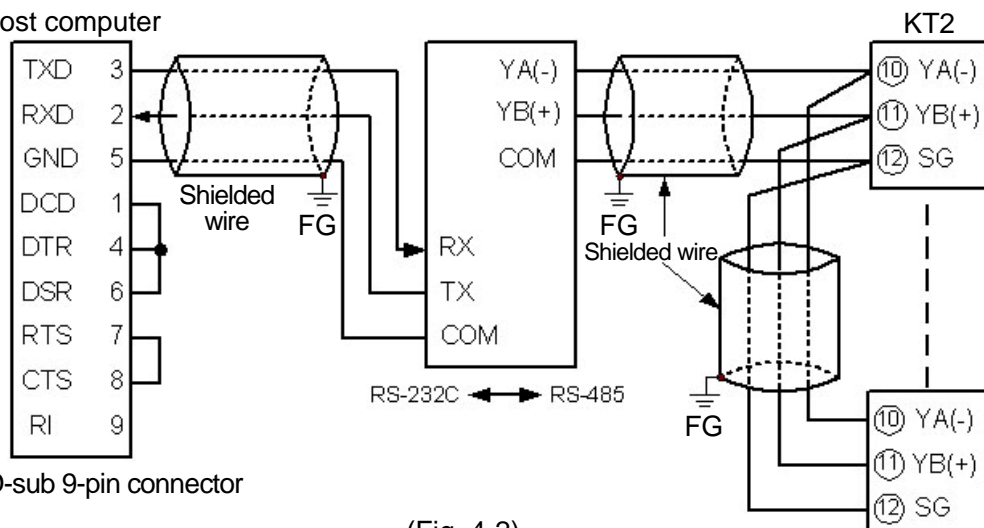

- Connector: D-sub 25-pin
- Connection: RS-232C ↔ RS-485 (Communication speed: 2400, 4800, 9600, 19200bps)

(Fig. 4-1)

- Connector: D-sub 9-pin
Connection: RS-232C ↔ RS-485 (Communication speed: 2400, 4800, 9600, 19200bps)

Host computer

(Fig. 4-2)

- When connecting PLC (RS-485)
Connection: RS-485 ↔ RS-485 (Communication speed: 2400, 4800, 9600, 19200bps)

(Fig. 4-3)

Shielded wire

Connect only one side of the shielded wire to the FG or GND terminal so that current cannot flow to the shielded wire. (If both sides of the shielded wire are connected to the FG or GND terminal, the circuit will be closed between the shielded wire and the ground. As a result, current will run through the shielded wire and this may cause noise.) Be sure to ground FG and GND terminals.

Terminator (Terminal resistor)

Do not connect terminator with the communication line because each KT2 has built-in pull-up and pull-down resistors instead of a terminator.

If there is a large distance between the PLC and the KT2, connect the terminator on the PLC side. (Connect a terminator of 120Ω or more resistance.)

Setup of the KT2

- It is necessary to set the instrument number individually to the KT2 when communicating by connecting plural units with serial communication.
Select a communication speed of KT2 in accordance with that of the host computer.
- For instrument number setting and communication speed selection, refer to Chapter "1. Setup of the KT2" or the instruction manual for KT2.

Memory capacity of the KT2

The memory can contain up to 1,000,000 (one million) set value entries. This memory capacity is sufficient when the set value is changed by keypad operation. However, when changing the set value via the communication function, be careful not to exceed the 1,000,000 (one million) capacity limit.

When Lock 1 or Lock 2 is used, every time the set value is changed by the communication function, the changed value is written in the non-volatile memory. If the value changed by the communication function is the same as previous one, then it is not written in the non-volatile memory.

When Lock 3 is used and if the set value is changed, the changed value is not written in the non-volatile memory until the power to the controller is turned off. This has no relation to the limit for changes in set value.

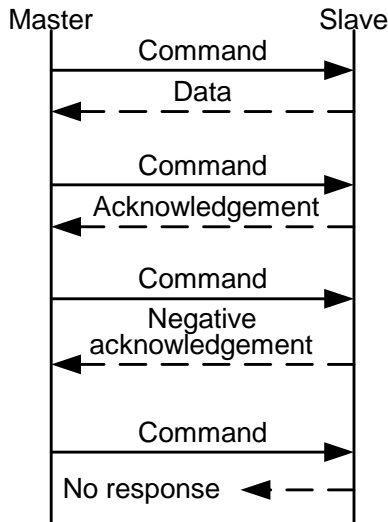

Therefore, be sure to use Lock 3 when changing the set value frequently via communication function.

SV2 of the KT2.

If communication function is applied to KT2, SV2 cannot be set by the command.

5. Communication procedure

Communication starts with command transmission from the host computer (hereafter Master) and ends with the response of the KT2 (hereafter Slave).

(Fig. 5-1)

- **Response with data**

When the master sends the reading command, the slave responds with the corresponding set value or current status.

- **Acknowledgement**

When the master sends the setting command, the slave responds by sending an acknowledgement after the processing is terminated.

- **Negative acknowledgement**

When the master sends a non-existent command or a value outside the setting range, the slave returns a negative acknowledgement.

- **No response**

The slave will not respond to the master when broadcast address is set, or when there is a communication error (framing error or parity error), or when LRC or CRC discrepancy is detected.

Communication timing of the RS-485

Slave side

When the slave starts transmission through the RS-485 communication line, the slave is arranged so as to provide an idle status (mark status) **transmission period of 1 or more characters** before sending the response to ensure the synchronization on the receiving side.

The slave is arranged so as to disconnect the transmitter from the communication line **within a 1 character transmission period** after sending the response.

Master side (Notice on programming)

Set the program so that the master can disconnect the transmitter from the communication line **within a 1 character transmission period** after sending the command in preparation for reception of the response from the slave.

To avoid the collision of transmissions between the master and the slave, send the next command after carefully checking that the master received the response.

6. Modbus protocol

6.1 Modbus protocol

Modbus protocol is a communication protocol for the PLC developed by Modicon Inc.

6.2 Transmission mode

There are 2 transmission modes (ASCII and RTU) in Modbus protocol.

6.3 ASCII mode

Hexadecimal (0 to 9, A to F), which is divided into high order (4-bit) and low order (4-bit) out of 8-bit binary data in the command is transmitted as ASCII characters.

Data format Start bit : 1 bit
 Data bit : 7 bits
 Parity : Even
 Stop bit : 1 bit
 Error detection: LRC (Longitudinal Redundancy Check)
 Data interval : 1 second or less

(1) Message configuration

ASCII mode message is configured to start by [: (colon)(3AH)] and end by [CR (carriage return) (0DH) + LF (Line feed)(0AH)]. (See Fig. 6.3-1)

Header (:)	Slave address	Function code	Data	Error check LRC	Delimiter (CR)	Delimiter (LF)
---------------	------------------	------------------	------	--------------------	-------------------	-------------------

(Fig. 6.3-1)

(2) Slave address

Slave address is an individual instrument number on the slave side and is set within the range 00H to 5FH (0 to 95).

The master identifies slaves by the slave address of the requested message.

The slave informs the master which slave is responding to the master by placing its own address in the response message.

[Slave address 00H (broadcast address) can identify all the slaves. However slaves do not respond.]

(3) Function code

The function code is the command code that makes the slave to undertake the following action types (Table 6.3-1). (Table 6.3-1)

Function code	Contents
03 (03H)	Reading the set value and information from slaves
06 (06H)	Setting to slaves

A function code is used to discern whether the response is normal (acknowledgement) or if any error (negative acknowledgement) has occurred when the slave returns the response message to the master.

When acknowledgement is returned, the slave simply returns the original function code.

When negative acknowledgement is returned, the MSB of the original function code is set as 1 for the response.

(For example, when the master sends a request message setting 10H to function code by mistake, slave returns 90H by setting the MSB to 1, because the former is an illegal function.)

For negative acknowledgement, exception code (Table 6.3-2) below is set to the data of response message and returned to the master in order to inform it that what kind of error has occurred.

(Table 6.3-2)

Exception code	Contents
1 (01H)	Illegal function (Non-existent function)
2 (02H)	Illegal data address (Non-existent data address)
3 (03H)	Illegal data value (Value out of the setting range)
17 (11H)	Illegal setting (Unsettable status)
18 (12H)	Illegal setting (During setting mode by keypad, etc)

(4) Data

Data differs depending on the function code.

A request message from the master is composed of data item, number of data and setting data.

A response message from the slave is composed of number of bytes, data and exception code in negative acknowledgement.

Effective range of data is -32768 to 32767 (8000H to 7FFFH).

(5) ASCII mode error check

After calculating LRC (Longitudinal Redundancy Check) from the slave address to the end of data, the calculated 8-bit data is converted to two ASCII characters and is appended to the end of the message.

How LRC is calculated

- ① Create a message in RTU mode.
- ② Add all the values from the slave address to the end of data. This is assumed as X.
- ③ Make a complement for X (bit reverse). This is assumed as X.
- ④ Add a value of 1 to X. This is assumed as X.
- ⑤ Set X as an LRC to the end of the message.
- ⑥ Convert the whole message to ASCII characters.

(6) ASCII mode message example

① Reading (Address 1, PV)

- A request message from the master

The number of data indicates the data item to be read and it is fixed as (30H 30H 30H 31H).

Header	Slave address	Function code	Data item	Number of data	Error check LRC	Delimiter	
(3AH)	(30H 31H)	(30H 33H)	(30H 30H 38H 30H)	(30H 30H 30H 31H)	(37H 42H)	(0DH 0AH)	Number of
1	2	2	4	4	2	2	← characters

(Fig. 6.3-2)

- A response message from the slave in normal status [When PV=600°C (0258H)]

The number of response bytes indicates the number of bytes of the data which has been read, and it is fixed as (30H 32H).

Header	Slave address	Function code	Number of response bytes	Data	Error check LRC	Delimiter	
(3AH)	(30H 31H)	(30H 33H)	(30H 32H)	(30H 32H 35H 38H)	(41H 30H)	(0DH 0AH)	Number of
1	2	2	2	4	2	2	← characters

(Fig.6.3-3)

- A response message from the slave in exception (error) status (When data item is mistaken)
The function code MSB is set to 1 for the response message in exception (error) status [83H (38H 33H)].
If an exception code [02H (30H 32H): Non-existent data address] is returned, the error can be determined by reading this code.

② Reading (Address 1, SV1)

- Request message from the master
The number of the data indicates the data item to be read and it is fixed as (30H 30H 30H 31H).

- A response message from the slave in normal status [When SV1=600°C (0258H)]
The number of response bytes indicates the number of bytes of the data which has been read, and it is fixed as (30H 32H).

- A response message from the slave in exception (error) status (When data item is mistaken)
The function code MSB is set to 1 for the response message in exception (error) status [83H (38H 33H)].
If an exception code [02H (30H 32H): Non-existent data address] is returned, the error can be determined by reading this code.

③ Setting (Address 1, SV1)

- A request message from the master: When setting SV1 to 600°C (0258H)

- A response message from the slave in normal status

- A response message from the slave in exception (error) status (When a value out of the setting range is set.)
The function code MSB is set to 1 for the response message in exception (error) status [86H (38H 36H)].
If an exception code [03H (30H 33H): Value out of the setting range] is returned, the error can be determined by reading this code.

6.4 RTU mode

8-bit binary data in command is transmitted as it is.

Data format	Start bit	: 1 bit
	Data bit	: 8 bits
	Parity	: No parity
	Stop bit	: 1 bit
	Error detection	: CRC-16 (Cyclic Redundancy Check)
	Data interval	: 3.5 characters transmission time or less

(1) Message configuration

RTU mode is configured to start after idle time is processed for more than 3.5 characters transmission and end after idle time is processed for more than 3.5 characters transmission. (See Fig. 6.4-1)

3.5 idle characters	Slave address	Function code	Data	Error check CRC	3.5 idle characters
---------------------	---------------	---------------	------	-----------------	---------------------

(Fig. 6.4-1)

(2) Slave address

Slave address is an individual instrument number on the slave side and is set within the range 00H to 5FH (0 to 95).

The master identifies slaves by the slave address of the requested message.

The slave informs the master which slave is responding to the master by placing its own address in the response message.

[Slave address 00H (broadcast address) can identify all the slaves. However slaves do not respond.]

(3) Function code

The function code is the command code that makes the slave undertake the following action types (Table 6.4-1).

Function code	Contents
03 (03H)	Reading the set value and information from slaves
06 (06H)	Setting to slaves

A function code is used to discern whether the response is normal (acknowledgement) or if any error (negative acknowledgement) has occurred when the slave returns the response message to the master. When acknowledgement is returned, the slave simply returns the original function code.

When negative acknowledgement is returned, the MSB of the original function code is set as 1 for the response.

(For example, when the master sends request message setting 10H to function code by mistake, slave returns 90H by setting the MSB to 1, because the former is an illegal function.)

For negative acknowledgement, exception code (Table 6.4-2) below is set to the data of response message and returned to the master in order to inform it that what kind of error has occurred.

(Table 6.4-2)

Exception code	Contents
1 (01H)	Illegal function (Non-existent function)
2 (02H)	Illegal data address (Non-existent data address)
3 (03H)	Illegal data value (Value out of the setting range)
17 (11H)	Illegal setting (Unsettable status)
18 (12H)	Illegal setting (During setting mode by keypad, etc)

(4) Data

Data differs depending on the function code.

A request message from the master side is composed of data item, number of data and setting data.

A response message from the slave side is composed of number of bytes, data and exception code in negative acknowledgement.

Effective range of data is -32768 to 32767 (8000H to 7FFFH).

(5) RTU mode error check

After calculating CRC-16 (Cyclic Redundancy Check) from the slave address to the end of data, the calculated 16-bit data is appended to the end of message in sequence from low order to high order.

How CRC is calculated

In the CRC system, the information is divided by a polynomial series. The remainder is added to the end of the information and then transmitted. The generation of the polynomial series is as follows.

(Generation of the polynomial series: $X^{16} + X^{15} + X^2 + 1$)

- ① Initialize the CRC-16 data (assumed as X) (FFFFH).
- ② Calculate exclusive OR (XOR) with the 1st data and X. This is assumed as X.
- ③ Shift X one bit to the right. This is assumed as X.
- ④ When a carry is generated as a result of the shift, XOR is calculated by X of ③ and the fixed value (A001H). This is assumed as X. If a carry is not generated, go to step ⑤.
- ⑤ Repeat steps ③ and ④ until shifting 8 times.

- ⑥ XOR is calculated with the next data and X. This is assumed as X.
- ⑦ Repeat steps ③ to ⑤.
- ⑧ Repeat steps ③ to ⑤ up to the last data.
- ⑨ Set X as CRC-16 to the end of message in sequence from low order to high order.

(6) RTU mode message example

① Reading (Address 1, PV)

- A request message from the master

The number of data indicates the data item to be read, and it is fixed as (0001H).

- Response message from the slave in normal status [When PV=600°C (0258H)]

The number of response bytes indicates number of bytes of the data which has been read, and it is fixed as (02H).

- Response message from the slave in exception (error) status (When data item is mistaken)

The function code MSB is set to 1 for the response message in exception (error) status (83H).
If an exception code (02H: Non-existent data address) is returned, the error can be determined by reading this code.

② Reading (Address 1, SV1)

- A request message from the master

The number of data indicates the data item to be read, and it is fixed as (0001H).

- Response message from the slave in normal status [SV1=600°C (0258H)]

The number of response bytes indicates number of bytes of the data which has been read, and it is fixed as (02H).

- Response message from the slave in exception (error) status (When data item is mistaken)

The function code MSB is set to 1 for the response message in exception (error) status (83H).
If an exception code (02H: Non-existent data address) is returned, the error can be determined by reading this code.

③ Setting (Address 1, SV1)

- A request message from the master: When setting SV1 to 600°C (0258H)

- Response message from the slave in normal status

- Response message from the slave in exception (error) status (When a value out of the setting range is set)
The function code MSB is set to 1 for the response message in exception (error) status (86H).
If an exception code (03H: Value out of the setting range) is returned, the error can be determined by reading this code.

7. Communication command table

Modbus function code	Data item	Data
03H/06H	1110H: Step 1 SV	Set value, Decimal point ignored

-----	---------------------------------------	---

8. Specifications

Communication method	: Half-duplex
Cable length	: Maximum communication distance 1,000m Cable resistance: Within 50Ω (The terminator is not necessary or 120Ω or more on the PLC side.)
Communication line	: EIA RS-485
Number of connectable units	: Maximum 31 units
Communication speed	: 9600bps (2400, 4800, 9600, 19200bps) Selectable by keypad
Synchronous system	: Start-stop synchronous
Instrument number	: 0 (0 to 95) Selectable by keypad
Communication protocol	: Modbus ASCII (Modbus ASCII, Modbus RTU) Selectable by keypad
Code form	: ASCII (Modbus ASCII), Binary (Modbus RTU) (*)
Error detection	: Parity, LRC (Modbus ASCII), CRC (Modbus RTU) (*)
Error correction	: Command request repeat system
Data format	Start bit : 1 bit Data bit : 7 bits (Modbus ASCII), 8 bits (Modbus RTU) (*) Parity : Even (Modbus ASCII), No parity (Modbus RTU) (*) Stop bit : 1 bit (*): Automatically selected upon selecting the communication protocol.

9. Troubleshooting

If any malfunction occurs, refer to the following items after checking the power supply to the master and the slave.

• Problem: Communication failure

Check the following
The connection or wiring of the communication cable is not secure.
Burnout or imperfect contact on the communication cable and the connector.
Communication speed of the slave does not coincide with that of the master.
The data bit, parity and stop bit of the master do not accord with those of the slave.
The instrument number of the slave does not coincide with that of the command.
The instrument numbers are duplicated in multiple slaves.
When communicating without using communication converter, make sure that the program is appropriate for the transmission timing.

• Problem: Although communication is occurring, the response is 'exception code'.

Check the following
Check whether a non-existent command code has been sent or not.
The setting command data exceeds the setting range of the slave.
The controller cannot be set when functions such as AT is performed.
While in setting mode and inputting settings via the front keypad.

For further inquiries, please consult our agency or the shop where you purchased the unit.
